Switch

Switch LAN SCION Access

Factsheet

More security, reliability and control: Switch LAN SCION access provides the best conditions for ensuring that your data is only transferred to the parts of the internet that you want it to reach.

The secure internet architecture of the next generation

These days, digitalisation requires secure networks that are easy to control. However, the foundation of the internet was laid last century without any special security mechanisms, and it has hardly been updated since. That makes it vulnerable. Nowadays, cybercriminals exploit vulnerabilities to such a degree that IT departments spend the majority of their time trying to prevent and eliminate cyber threats. This observation concerns not only the multitude of security risks, but also aspects of the transport network. It's high time for an upgrade. SCION (Scalability, Control, and Isolation On Next-Generation Networks) is that upgrade. Switch LAN SCION access combines the security, reliability and control of private networks with the flexibility of the public internet. The technology was developed at the Swiss Federal Institute of Technology (ETH) in Zurich. Switch has supported SCION's development at ETH Zurich since 2015.

How you benefit

Security by design

Switch LAN SCION access protects against cyber attacks such as prefix hijacking and specific DDoS attacks

New security features

Path control and path verification

Path control

You define the networks to which your data is confined; you define the route your data packets take

Path verification

The path and integrity of all packages is crytographically secured and verifiable

Multi-pathing

Reliable data transfer via multiple network paths at the same time

Cybersecurity

Your data can no longer be redirected during transfers; protection against DDoS reflection attacks

Isolation domains

Trust limited to participants of an ISD (no more global trust roots)

High degree of reliability

SCION's architecture gives you a high degree of reliability with various features and new concepts. As a result, some attacks can be prevented from the very outset: SCION is immune to prefix hijacking. What is more, the technology reduces the risk of exposure to distributed denial of service (DDoS) attacks through hidden paths and source authentication. The protection provided against address spoofing even prevents susceptibility to DDoS reflection attacks.

Reliability and performance through multi-pathing

Multi-pathing allows the SCION protocol to open up multiple potential paths that can be used simultaneously. This increases the usable capacity in the network and enables faster switching in the event of path failures, provided that the application supports this function. In this instance, the granularity of the path selection is restricted to the transfer points between networks (autonomous systems). The path within a network is not subject to the control of SCION, meaning alternative paths cannot be used there.

More control with SCION

SCION gives you path control over your end-to-end communication, allowing you to avoid certain network sections such as networks in unstable regions. Control over path choice also allows you to make selections regarding available bandwidths and latencies. This increases the security of your data in terms of how it is handled. You get more control over the transport route of your sensitive data.

Security

All the paths are authenticated and protected against routing attacks.

Control

You control the route of your data to its destination.

Performance

A SCION application can select the best paths for network traffic based on cost or latency rules.

Stability

Multiple network paths with instant failover ensure that individual path failures go unnoticed.

Protection

Hidden paths and the path selection controlled by the sender increase protection against DDoS attacks.

The technology of SCION

Today's internet is made up of a multitude of loosely interconnected networks. Communication between the different networks makes transfers vulnerable through route hijacking. For example, a data packet could be diverted across several countries on its way from Zurich to Geneva and the sender and recipient would be helpless to prevent this from happening. Such hijackings are often detected well after the event.

Cybercriminals can redirect data packets or disable internet services with DDoS attacks. This is where SCION comes in – and minimises the area of attack to network level from the outset.

A team from ETH Zurich has redesigned SCION's internet architecture from scratch. The foundation is formed by 'isolation domains' (ISDs). These domains can be states, industries or autonomous companies. SCION combines several networks (geographical, for example) to form ISDs. All the Swiss networks can belong to one ISD, for instance. Communication between two networks in the same ISD never goes anywhere else. As a result, confidential data can no longer be diverted unchecked via other network sections.

With SCION, the sender determines what transport route the data packets take, making attacks at routing level essentially impossible. For example, you can specify certain providers or network paths to avoid.

At present, the SCION protocol is still in development. Officially, the specification has not yet been publicly standardised. The development team at ETH is actively seeking to obtain this standardisation.

Services

Switch LAN SCION Access

This variant is your SCION connection to Switch LAN's SCION Core (CH-ISD, without Edge services). Here, you the customer are responsible for procuring and operating the SCION router. You will need a software licence for this, depending on the provider.

Switch LAN SCION Edge

The managed service is an optional addition to Switch LAN SCION access and is used to operate your SCION router and connection (SCION Edge: SCION IP gateway). If you are not connected to the Switch LAN backbone yet, for example because you are using the IP access or L2VPN service, we will be happy to provide you with a tailored quotation.
